Lecture 13 October 25, 2024

Type Checking

- Lock is type, key is operation
 - Example: UNIX system call write won't work on directory object but does work on file
 - Example: split I&D space of PDP-11
 - Example: countering buffer overflow attacks on the stack by putting stack on non-executable pages/segments
 - Then code uploaded to buffer won't execute
 - Does not stop other forms of this attack, though ...

More Examples

- LOCK system:
 - Compiler produces "data"
 - Trusted process must change this type to "executable" before program can be executed
- Sidewinder firewall
 - Subjects assigned domain, objects assigned type
 - Example: ingress packets get one type, egress packets another
 - All actions controlled by type, so ingress packets cannot masquerade as egress packets (and vice versa)

Sharing Secrets

- Implements separation of privilege
- Use (t, n)-threshold scheme
 - Data divided into *n* parts
 - Any t parts sufficient to derive original data
- Or-access and and-access can do this
 - Increases the number of representations of data rapidly as n, t grow
 - Cryptographic approaches more common

Shamir's Scheme

- Goal: use (t, n)-threshold scheme to share cryptographic key encoding data
 - Based on Lagrange polynomials
 - Idea: take polynomial p(x) of degree t-1, set constant term (p(0)) to key
 - Compute value of p at n points, excluding x = 0
 - By algebra, need values of p at any t distinct points to derive polynomial, and hence constant term (key)

Reference Monitor

- Reference monitor is access control concept of an abstract machine that mediates all accesses to objects by subjects
- Reference validation mechanism (RVM) is an implementation of the reference monitor concept.
 - Tamperproof
 - Complete (always invoked and can never be bypassed)
 - Simple (small enough to be subject to analysis and testing, the completeness of which can be assured)
 - Last engenders trust by providing evidence of correctness
- Note: RVM is almost always called a reference monitor too

Examples (Or, What Should Be Examples)

- Security kernel combines hardware and software to implement reference monitor
- Trusted computing base (TCB) consists of all protection mechanisms within a system responsible for enforcing security policy
 - Includes hardware and software
 - Generalizes notion of security kernel

Policy and Reference Monitor

- Reference monitor implements a given policy
 - It has a tamperproof authorization database
 - Also maintains an audit trail (record of security-related events) for review

Example Problem

- Server balances bank accounts for clients
- Server security issues:
 - Record correctly who used it
 - Send only balancing info to client
- Client security issues:
 - Log use correctly
 - Do not save or retransmit data client sends

Generalization

- Client sends request, data to server
- Server performs some function on data
- Server returns result to client
- Access controls:
 - Server must ensure the resources it accesses on behalf of client include only resources client is authorized to access
 - Server must ensure it does not reveal client's data to any entity not authorized to see the client's data

Confinement Problem

 Problem of preventing a server from leaking information that the user of the service considers confidential

Total Isolation

- Process cannot communicate with any other process
- Process cannot be observed

Impossible for this process to leak information

• Not practical as process uses observable resources such as CPU, secondary storage, networks, etc.

Example

- Processes p, q not allowed to communicate
 - But they share a file system
- Communications protocol:
 - p sends a bit by creating a file called 0 or 1, then a second file called send
 - p waits until send is deleted before repeating to send another bit
 - q waits until file send exists, then looks for file 0 or 1; whichever exists is the bit
 - q then deletes 0, 1, and send and waits until send is recreated before repeating to read another bit

Covert Channel

- A path of communication not designed to be used for communication
- In example, file system is a (storage) covert channel

Rule of Transitive Confinement

- If p is confined to prevent leaking, and it invokes q, then q must be similarly confined to prevent leaking
- Rule: if a confined process invokes a second process, the second process must be as confined as the first

Isolation

- Constrain process execution in such a way it can only interact with other entities in a manner preserving isolation
 - Hardware isolation
 - Virtual machines
 - Library operating systems
 - Sandboxes
- Modify program or process so that its actions will preserve isolation
 - Program rewriting
 - Compiling
 - Loading

Hardware Isolation

- Ensure the hardware is disconnected from any other system
 - This includes networking, including wireless
- Example: SCADA systems
 - 1st generation: serial protocols, not connected to other systems or networks; no security defenses needed, focus being on malfunctions
 - 2nd generation: serial networks connected to computers not connected to Internet
 - 3rd generation: TCP/IP protocol running on networks connected to Internet; need security defenses for attackers coming in over Internet
- Example: electronic voting systems
 - Physical isolation protects systems from attackers changing votes remotely
 - Required in many U.S. states, such as California: never connect them to any network

Virtual Machine

- Program that simulates hardware of a machine
 - Machine may be an existing, physical one or an abstract one
 - Uses special operating system, called *virtual machine monitor* (*VMM*) or *hypervisor*, to provide environment simulating target machine
- Types of virtual machines
 - Type 1 hypervisor: runs directly on hardware
 - Type 2 hypervisor: runs on another operating system
- Existing OSes do not need to be modified
 - Run under VMM, which enforces security policy
 - Effectively, VMM is a security kernel

VH _i is virtual machine <i>i</i> T2H _i is type-2 hypervisor <i>i</i>			Debian Linux	Windows XP			
			VH_A	VH_B			
user procs	user procs	user procs	T2H _A	T2H _B	user procs	user procs	user procs
Ubuntu Linux	FreeBSD	s0/z	Windows 10	Ubuntu Linux	FreeBSD	z/0S	Windows 10
	_			VH ₅	VH ₆	VH ₇	VH ₈
VH ₁	VH ₂	VH ₃	VH ₄	T2H ₁	T2H ₂		T2H ₃
Type-1 Hypervisor				Operating System			
Physical Hardware				Physical Hardware			

VMM as Security Kernel

- VMM deals with subjects (the VMs)
 - Knows nothing about the processes within the VM
- VMM applies security checks to subjects
 - By transitivity, these controls apply to processes on VMs
- Thus, satisfies rule of transitive confinement

Example: Xen Hypervisor

- Xen 3.0 hypervisor on Intel virtualization technology
- Two modes, VMX root and non-root operation
- Hardware-based VMs (HVMs) are fully virtualized domains, support unmodified guest operating systems and run in non-root operation mode
 - Xen hypervisor runs in VMX root mode
- 8 levels of privilege
 - 4 in VMX root operation mode
 - 4 in VMX root operation mode
 - No need to virtualize one of the privilege levels!

Xen and Privileged Instructions

- Guest operating system executes privileged instruction
 - But this can only be done as a VMX root operation
- Control transfers to Xen hypervisor (called VM exit)
- Hypervisor determines whether to execute instruction
- After, it updates HVM appropriately and returns control to guest operating system (called VM entry)

Problem

- Physical resources shared
 - System CPU, disks, etc.
- May share logical resources
 - Depends on how system is implemented
- Allows covert channels

Sandboxes

- An environment in which actions are restricted in accordance with security policy
 - Limit execution environment as needed
 - Program not modified
 - Libraries, kernel modified to restrict actions
 - Modify program to check, restrict actions
 - Like dynamic debuggers, profilers

Example: Capsicum

- Framework developed to sandbox an application
- Capability provides fine-grained rights for accessing, manipulating underlying file
- To enter sandbox (capability mode), process issues cap_enter
- Given file descriptor, create capability with cap_new
 - Mask of rights indicates what rights are to be set; if capability exists, mask must be subset of rights in that capability
- At user level, library provides interface to start sandboxed process and delegate rights to it
 - All nondelegated file descriptors closed
 - Address space flushed
 - Socket returned to creator to enable it to communicate with new process

Example: Capsicum (con't)

- Global namespaces not available
 - So system calls that depend on that (like open(2)) don't work
 - Need to use a modified open that takes file descriptor for containing directory
 - Other system calls modified appropriately
 - System calls creating memory objects can create anonymous ones, not named ones (as those names are in global namespace)
- Subprocesses cannot escalate privileges
 - But a privileged process can enter capability mode
- All restrictions applied in kernel, not at system call interface

Program Confinement and TCB

- Confinement mechanisms part of trusted computing bases
 - On failure, less protection than security officers, users believe
 - "False sense of security"
- Must ensure confinement mechanism correctly implements desired security policy

Covert Channels

- Shared resources as communication paths
- Covert storage channel uses attribute of shared resource
 - Disk space, message size, etc.
- Covert timing channel uses temporal or ordering relationship among accesses to shared resource
 - Regulating CPU usage, order of reads on disk

Example Storage Channel

- Processes p, q not allowed to communicate
 - But they share a file system!
- Communications protocol:
 - p sends a bit by creating a file called 0 or 1, then a second file called send
 - p waits until send is deleted before repeating to send another bit
 - q waits until file send exists, then looks for file 0 or 1; whichever exists is the bit
 - q then deletes 0, 1, and send and waits until send is recreated before repeating to read another bit

Example Timing Channel

- System has two VMs
 - Sending machine S, receiving machine R
- To send:
 - For 0, S immediately relinquishes CPU
 - For example, run a process that instantly blocks
 - For 1, S uses full quantum
 - For example, run a CPU-intensive process
- R measures how quickly it gets CPU
 - Uses real-time clock to measure intervals between access to shared resource (CPU)

Example Covert Channel

- Uses ordering of events; does not use clock
- Two VMs sharing disk cylinders 100 to 200
 - SCAN algorithm schedules disk accesses
 - One VM is High (H), other is Low (L)
- Idea: L will issue requests for blocks on cylinders 139 and 161 to be read
 - If read as 139, then 161, it's a 1 bit
 - If read as 161, then 139, it's a 0 bit

How It Works

- L issues read for data on cylinder 150
 - Relinquishes CPU when done; arm now at 150
- H runs, issues read for data on cylinder 140
 - Relinquishes CPU when done; arm now at 140
- L runs, issues read for data on cylinders 139 and 161
 - Due to SCAN, reads 139 first, then 161
 - This corresponds to a 1
- To send a 0, H would have issued read for data on cylinder 160

Noisy vs. Noiseless

- Noiseless: covert channel uses resource available only to sender, receiver
- Noisy: covert channel uses resource available to others as well as to sender, receiver
 - Idea is that others can contribute extraneous information that receiver must filter out to "read" sender's communication

Defending Against Covert Channels

- Add lots of noise
 - The idea is to prevent the receiver from being able to pick up the signal the sender is sending
- Make the events regular
 - Similar to adding noise, this hides the signal in the regularity
